#### Flows

# More Flow

The Maximum Flow Problem

c. Find a flow whose value is maximum.

#### Flows

• An important value we will be worried about is the value of flow  $f = |f| = \sum_{v \in V} f(s, v)$ : The total flow out of the source.

Given G = (V, E). source node  $s \in V$ , sink node  $t \in V$ , edge capacities

## Lemma, Lemma, Lemma

#### Recall Shorthand

$$f(X,Y) = \sum_{x \in X} \sum_{y \in Y} f(x,y).$$

- $f(X,X) = 0 \ \forall X \subseteq V$
- $f(X,Y) = -f(Y,X) \ \forall X,Y \subseteq V$
- $\begin{tabular}{ll} \hline {\bf O} & {\rm Let} \ X,Y,Z\subset V \ {\rm be \ such \ that} \ X\cap Y=\emptyset, \ {\rm then} \ \end{tabular} \end{tabular}$

$$f(X \cup Y, Z) = f(X, Z) + f(Y, Z)$$
  
$$f(Z, X \cup Y) = f(Z, X) + f(Z, Y)$$

|f| = f(V,t)

Cuts

## A Simple Upper Bound

- A cut of a (flow) network G = (V, E) is a partition of V into S and  $T = V \setminus S$  such that  $s \in S$  and  $t \in T$
- For flow f, net flow across a cut is f(S,T) and the cuts capacity is  $c(S,T)=\sum_{u\in S}\sum_{v\in T}c(u,v)$
- A minimum cut of G is a cut whose capacity is minimum

Flow Across Cuts Lemma

• For any cut (S,T), f(S,T) = |f|

Coronary :-)

The value of any flow is no more than the capacity of any cut

$$|f| = f(S,T) = \sum_{u \in S} \sum_{v \in T} f(u,v) \le \sum_{u \in S} \sum_{v \in T} c(u,v) = c(S,T).$$

#### Ford-Fulkerson Method

#### **Residual Capacity**

- Given a flow f in a network G = (V, E), we ask ourselves the question: How much more flow can I push from  $u \in V$  to  $v \in V$ ?
- The answer is simple: The residual capacity of the arc (u, v):

$$c_f(u,v) \stackrel{\text{def}}{=} c(u,v) - f(u,v) \ge 0.$$

- Note: f(v, u) might be < 0. (like if f(u, v) > 0).
- So if "no" original arc (v, u), and flow from (u, v),  $f(v, u) < 0 \Rightarrow$  residual capacity!
- $\bullet~$  We can "increase" the flow from (v,u) by reducing the from from (u,v)

# **Residual Network**

• Give flow f, we can create a residual network from the flow.  $G_f=(V,E_f),$  with

Ford-Fulkerson Method

$$E_f \stackrel{\text{def}}{=} \{(u,v) \in V \times V \mid c_f(u,v) > 0\},\$$

so that each edge in the residual network can admit a positive flow.

 So if there is a path from s → t in G<sub>f</sub>, then there must be a way to increase the flow without violating the capacity constraints on any of the edges

|                                    |                     |         |               |        |                                    |           |         |               |         |

## Augmenting Flow Lemma

• We define the flow sum of two flows  $f_1$ ,  $f_2$  as the sum of the individual flows

$$(f_1 + f_2)(u, v) = f_1(u, v) + f_2(u, v).$$

- Note that  $f_1 + f_2$  is also a flow function
- Moreover, we have the following:

#### Flow Sum Lemma (26.2)

Given a flow network G, a flow f in G. Let f' be any flow in the residual network  $G_f$ . Then the flow sum f + f' is a flow in G with value |f| + |f'|

# Augmenting Paths

- Consider a path  $P_{st}$  from s to t in  $G_f$ .
- According to the lemma, we can increase the flow in G by increasing the flow along each edge in  ${\cal P}_{st}$
- Think of it as a sequence of pipes along which we can squirt more flow from s to t
- How much more? Simple:  $c_f(P_{st}) = \min\{c_f(u, v) \mid (u, v) \text{ is on } P_{st}.$

#### Ford-Fulkerson Method

#### Augmenting Paths

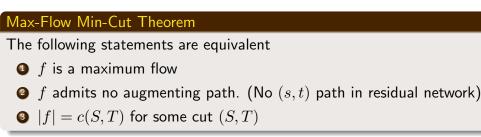

## The Big Kahuna

• Augmenting flow: Let P be an augmenting path in  $G_f$ , define  $f_P: V \times V \to \mathbb{R}^{|V| \times |V|}$ :

$$f_P(u,v) = \begin{cases} c_f(p) & (u,v) \text{ on } P\\ -c_f(p) & (v,u) \text{ on } P\\ 0 & \text{ otherwise} \end{cases}$$

then  $f_P$  is a flow in  $G_f$  with value  $|f_P| = c_f(P) > 0$ • corollary:  $f' = f + f_P$  is a flow in G with value  $|f'| = |f| + c_f(P) > |f|$ 

Ford-Fulkerson Method

## Proof of MFMC

- (1) ⇒ (2). By contradiction. If f has an augmenting path, then the flow can't have been maximum (by previous corollary)
- (2)  $\Rightarrow$  (3). Let

$$S = \{v \in V \mid \exists \text{ path from } s \text{ to } v \text{ in } G_f\}.$$
  
$$T = V \setminus S.$$

Note that  $t \in T$  or else there was an augmenting path, so (S,T) is a cut. For each  $u \in S, v \in T$ , f(u,v) = c(u,v) or otherwise  $(u,v) \in E_f$  and we should have put  $v \in S$ . Therefore |f| = f(S,T) = c(S,T) for the chosen cut (S,T)

• (3)  $\Rightarrow$  (1). Since  $|f| \le c(S,T)$  (always), the fact that |f| = c(S,T) for the chosen cut implies that f must be a maximum flow.

Quite Enough Dove

## Ford-Fulkerson Algorithm

• This gave Lester Ford and Del Fulkerson an idea to find he maximum flow in a network:

FORD-FULKERSON(V, E, c, s, t)

- 1 for  $i \leftarrow 1$  to n
- 2 **do**  $f[u,v] \leftarrow f[v,u] \leftarrow 0$
- 3 while  $\exists$  augmenting path P in  $G_f$
- 4 **do** augment f by  $c_f(P)$
- Assume all capacities are integers. If they are rational numbers, scale them to be integers.

Can We Do Better!? – Edmonds-Karp

#### Ford-Fulkerson Method

#### Analysis

- If the maximum flow is  $|f|^*$ , then (since the augmenting path must raise the flow by at least 1 on each iteration), we will require  $\leq |f|^*$  iterations.
- Augmenting the flow takes O(|E|)
- FORD-FULKERSON runs in  $O(|f|^*|E|)$
- This is not polynomial in the size of the input.
- If you augment flow along the path with largest residual capacity, one can show that at most  $O(|E| \lg U)$  iterations are needed.
  - $U = \max_{(u,v) \in V \times V} c(u,v)$
- The "greedy" (maximum capacity) aumenting path algorithm runs in  $O(|E|^2 \lg U)$ . This is polynomial in the size of the input, but not strongly polynomial (It still depends on the magnitude of the "numbers" in the instance, not on the size of the instance itself).

- Instead of augmenting on an *arbitrary* augmenting path, why don't we augment flow along the shortest augmenting path.
- Here shortest means simply number of edges taken, so all edges have weight 1.
- Therefore shortest pahs can be found just like you did in lab with BFS
- With some heavy machinery (See book), one can show that if you only augment on shortest paths, then you have to do at most O(|V||E|) augmentations of the flow
- Therefore Edmonds-Karp algorithm runs in  $O(|V||E|^2)$  time.
- There are even faster algorithms, such as push-relabel, but we won't cover those.

|                                    |                    |                       |                                    |                    |                    |      |

#### Maximum Bipartite Matching

# Applications

- A graph G = (V, E) is bipartite if we can partition the vertices into V = L ∪ R such that all edges in E go between L and R
- A matching is a subset of edges  $M \subseteq E$  such that for all  $v \in V$ ,  $\leq 1$  edge of M is incident upon it.

#### Maximum Bipartite Matching

Given (undirected) bipartite graph  $G = (L \cup R, E)$ , find a matching M of G that contains the most edges

There are lots of applications of matching problems

- Airlines
  - L set of planes
  - R set of routes
  - $(u,v) \in E$  if plane u can fly route v
  - Maximize the number of routes served by planes

#### Bipartite Matching

#### Solving It

Observations

- Bipartite matching is one of many problems that can be equivalently formulated (and solved) via maximum flows.
- Given  $G = (L \cup R, E)$ , create flow network G' = (V', E')
  - $V' = V \cup \{s, t\}$
  - $E' = \{(s, u) \mid u \in L\} \cup E \cup \{(v, t) \mid v \in R\}$
  - $c(u,v) = 1 \ \forall (u,v) \in E'$

(You can see the book for more formal proofs)

- There is a matching M in G of size |M| if and only if there is an (integer-valued) flow f in G' of value |f| = |M|.
- Thus a maximum-matching in a bipartite graph G is the value of the maximum flow in the flow network G'
- What is a cut in G'?
